1 Project Description and Impact Summary

1.1 Introduction

This study analyzes the potential noise and vibration impacts of the proposed MetroWalk project (herein referred to as “proposed project” or “project”) in Santa Clarita, California. Rincon Consultants, Inc. (Rincon) prepared this study for BluMax Santa Clarita, LLC for use in support of environmental documentation being prepared for the project pursuant to the California Environmental Quality Act (CEQA). The purpose of this study is to analyze the project’s noise and vibration impacts related to both temporary construction activity and long-term operation of the project.

1.2 Project Summary

Project Location

The project site is an approximately 20.4-acre undeveloped parcel (Assessor’s Parcel Number 2840-004-009) located east of Lost Canyon Road and south of the Vista Canyon Mixed-Use Project in Santa Clarita, California. State Route (SR) 14 is located approximately 0.3 mile west of the project site and provides regional access to the area. The project site has a General Plan Land Use designation of Business Park (BP) and is zoned Business Park (BP). The project would require a General Plan Amendment and Zone Change to accommodate the proposed residential development. Figure 1 shows the regional location of the project site, and Figure 2 shows an aerial view of the project site and surrounding area.

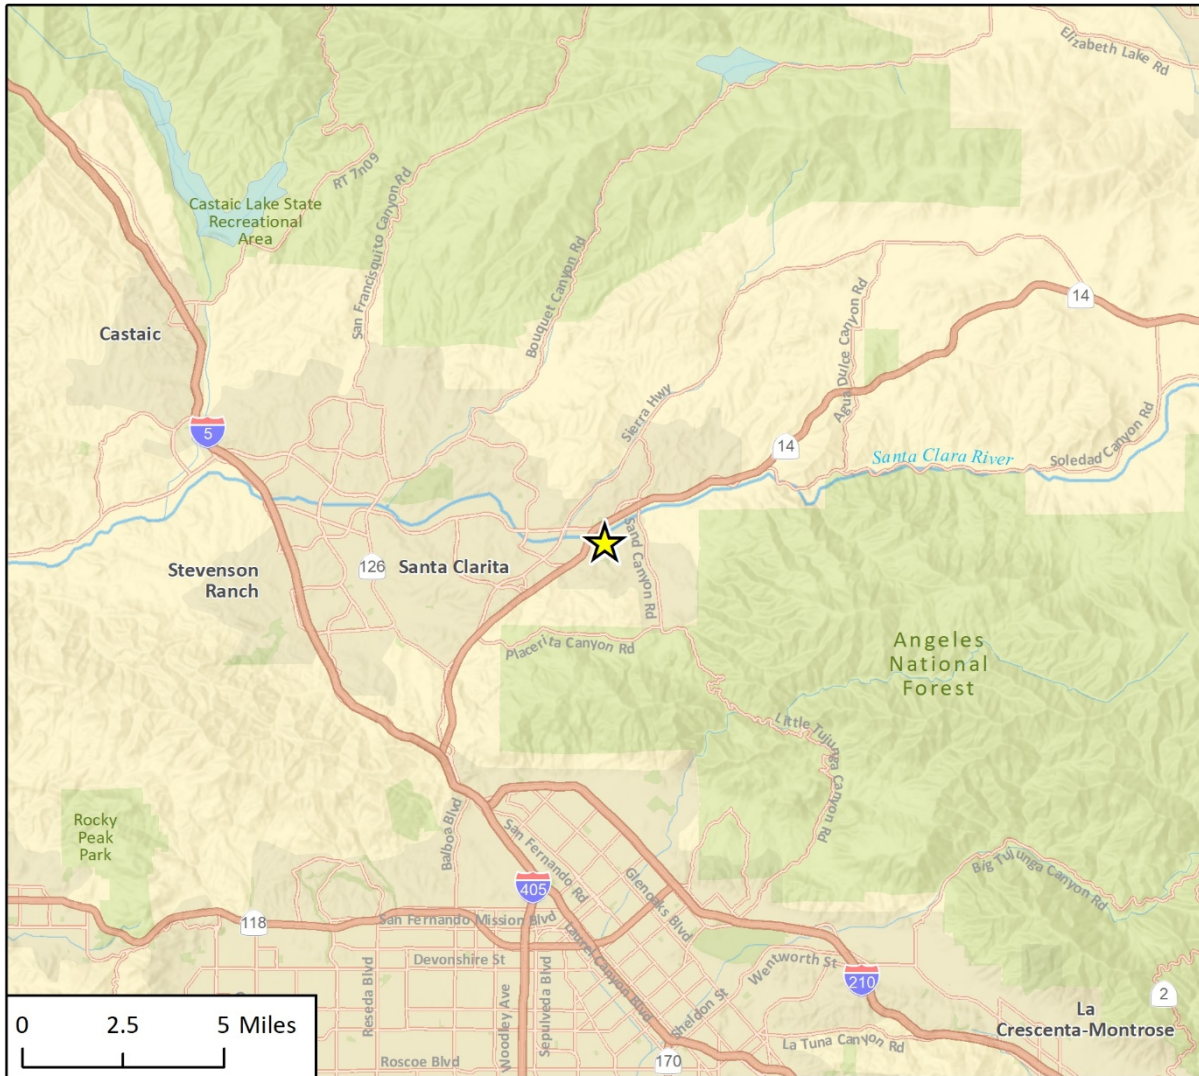

Surrounding land uses include the 185-acre Vista Canyon Mixed-Use Project currently under construction to the north and single-family residences to the south, west, and east. The Vista Canyon Mixed-Use Project will consist of residential, commercial, office, retail, and hotel uses in addition to open space, parks, and trails. A multi-modal transit hub for Metrolink, parking, and bus transfers is also planned to be sited adjacent to the project site and the Vista Canyon Mixed-Use Project.

Union Pacific Railroad tracks are located immediately south of the project site and provide service for the Metrolink Antelope Valley Line, which is a commuter rail line from Lancaster to Los Angeles Union Station. In addition, an approximately 14-acre ranch with a rural residential home is located approximately 0.1 mile to the east.

Project Description

The proposed project would involve construction of a mixed-income residential development with a total of 498 units. As shown in Table 1, the project would include 179 multi-family residential units, 169 age-qualified apartments (50 of which would be affordable senior housing units), and 150 three-story townhomes. The proposed project would also provide approximately 147,665 square feet (SF) of parks, clubrooms, pools, and landscaped walkways in addition to approximately 63,506 SF of rear yards and private patio decks. In addition, as shown in Table 2, the project would include

Figure 1 Regional Location

approximately 902 parking spaces with 631 garage/covered spaces and 271 uncovered/surface parking spaces. Figure 3 presents the project site plan.

Table 1 Project Summary

Unit Type	Square Footage per Unit	Number of Units
Market Rate All-Ages Apartments		
Studio + 1 Bath	500	26
1 Bed + 1 Bath	678	116
2 Bed + 2 Bath	1,041	37
Total		179
Age-Qualified Apartments		
1 Bed +1 Bath	678	84
2 Bed + 2 Bath	1,041	35
Total		119
Deed Restricted Affordable Senior Apartments		
1 Bed +1 Bath	650	49
2 Bed + 2 Bath (Manager's)	950	1
Total		50
Townhomes		
2 Bed + 2.5 Bath	1,340 – 1,365	59
3 Bed + 2 Full Bath + 2 Half Bath	1,753 – 1,998	85
3 Bed + 2.5 Bath	2,292	6
Total		150
Total Multi-family Residential Units		498

Table 2 Parking Summary

Type of Parking	Number of Spaces
Apartments	331 Covered 196 Uncovered
Townhomes	300 Private Garage 75 Uncovered
Parking Spaces Subtotal	631 Covered/Garage 271 Uncovered
Total Parking	902 Spaces

Construction

Project construction is expected to commence in March 2022 with full buildout of all phases completed by mid- to late 2027. Site preparation of the site would occur over the course of the first two months and grading and drainage/utilities installation would occur over the next nine months. Paving would occur over two weeks. Buildings would then be constructed in phases over the course of 36 months, starting with construction of the multi-family apartments and townhomes, followed by the age-qualified apartments and the senior affordable housing units. Architectural coating would occur over the course of 10 months for each phase. No demolition activities would be required.

Construction activities would occur between the hours of 7:00 a.m. and 7:00 p.m., Monday through Friday, and 8:00 a.m. to 6:00 p.m. on Saturday. Santa Clarita Municipal Code (SCMC) Section 11.44.080 indicates construction work is prohibited on Sundays, New Year's Day, Independence Day, Thanksgiving Day, Christmas Day, Memorial Day, and Labor Day. The project would consist of approximately 400,000 cubic yards of cut, up to 400,000 cubic yards of fill, and approximately 400,000 cubic yards of remedial grading. No dirt would be hauled on or off the site. Construction waste from the project site would be hauled to Chiquita Canyon Landfill, approximately 15 to 20 miles west of the project site, depending on the route taken. The following three haul truck routes could be used:¹

- Trucks could leave the project site by turning left onto Lost Canyon Road, taking State Route 14 south, to Interstate 5 north, and to State Route 126 west to the landfill site.
- Trucks could leave the project site by turning left onto Lost Canyon Road, left onto Soledad Canyon Road and Newhall Ranch Road, and to State Route 126 west to the landfill site.
- Trucks could leave the project site by turning left onto Lost Canyon Road, to Golden Valley Road, to Newhall Ranch Road, and to State Route 126 west to the landfill site.

Sustainability Features

The project would be built in accordance with the City of Santa Clarita Green Building Code (Santa Clarita Municipal Code Title 25, Chapter 25.01), which adopted by reference the 2019 California Green Building Standards Code [CALGreen] as well as the City of Santa Clarita Energy Conservation Code (Santa Clarita Municipal Code Title 24), which adopts by reference the 2019 Building Energy Efficiency Standards Code. In addition, as project design features, the project would install light-emitting diode (LED) streetlights, utilize reclaimed water for all landscape irrigation, and include approximately 54 electric vehicle (EV) charging spaces capable of supporting future EV supply equipment for multi-family residential units and approximately 150 EV spaces with the capability for EV charging for townhomes.

¹ To provide a conservative estimate of project emissions, this analysis assumes the longest 20-mile haul route would be used.

2 Background

2.1 Overview of Sound Measurement

Sound is a vibratory air disturbance created by a moving or vibrating source, which is capable of being detected by the hearing organs (e.g., the human ear). Noise is defined as sound that is loud, unpleasant, unexpected, or undesired and may therefore be classified as a more specific group of sounds. The effects of noise on people can include general annoyance, interference with speech communication, sleep disturbance, and, in the extreme, hearing impairment (California Department of Transportation [Caltrans] 2013).

Noise levels are commonly measured in decibels (dB) using the A-weighted sound pressure level (dBA). The A-weighting scale is an adjustment to the actual sound pressure levels so that they are consistent with the human hearing response, which is most sensitive to frequencies around 4,000 Hertz (Hz) and less sensitive to frequencies around and below 100 Hz (Kinsler, et al. 1999). Decibels are measured on a logarithmic scale that quantifies sound intensity in a manner similar to the Richter scale used to measure earthquake magnitudes. A doubling of the energy of a noise source, such as a doubling of traffic volume, would increase the noise level by 3 dB; similarly, dividing the energy in half would result in a decrease of 3 dB (Crocker 2007).

Human perception of noise has no simple correlation with sound energy; the perception of sound is not linear in terms of dBA or in terms of sound energy. Two sources do not “sound twice as loud” as one source. It is widely accepted that the average healthy ear can barely perceive an increase (or decrease) of up to 3 dBA in noise levels (i.e., twice [or half] the sound energy); that a change of 5 dBA is readily perceptible (8 times the sound energy); and that an increase (or decrease) of 10 dBA sounds twice (or half) as loud (10.5 times the sound energy) (Crocker 2007).

Sound changes in both level and frequency spectrum as it travels from the source to the receiver. The most obvious change is the decrease in sound level as the distance from the source increases. The manner by which noise reduces with distance depends on factors such as the type of sources (e.g., point or line), the path the sound will travel, site conditions, and obstructions. Noise levels from a point source (e.g., construction, industrial machinery, ventilation units) typically attenuate, or drop off, at a rate of 6 dBA per doubling of distance. Noise from a line source (e.g., roadway, pipeline, railroad) typically attenuates at about 3 dBA per doubling of distance (Caltrans 2013). The propagation of noise is also affected by the intervening ground, known as ground absorption. A hard site, such as a parking lot or smooth body of water, receives no additional ground attenuation, and the changes in noise levels with distance (drop-off rate) result simply from the geometric spreading of the source. An additional ground attenuation value of 1.5 dBA per doubling of distance applies to a soft site (e.g., soft dirt, grass, or scattered bushes and trees) (Caltrans 2013).

Noise levels may also be reduced by intervening structures; the amount of attenuation provided by this “shielding” depends on the size of the object and the frequencies of the noise levels. Natural terrain features, such as hills and dense woods, and man-made features, such as buildings and walls, can significantly alter noise levels. Generally, any large structure blocking the line of sight will provide at least a 5-dBA reduction in source noise levels at the receiver (Federal Highway Administration [FHWA] 2011). Structures can substantially reduce occupants’ exposure to noise as well. The FHWA’s guidelines indicate that modern building construction generally provides an exterior-to-interior noise level reduction of 20 to 35 dBA with closed windows.

The impact of noise is not a function of sound level alone. The time of day when noise occurs, and the duration of the noise are also important. Most noise that lasts for more than a few seconds is variable in its intensity. Consequently, a variety of noise descriptors have been developed. One of the most frequently used noise metrics is the equivalent noise level (L_{eq}); it considers both duration and sound power level. The L_{eq} is defined as the single steady A-weighted level equivalent to the same amount of energy as that contained in the actual fluctuating levels over a period of time. Typically, the L_{eq} is summed over a one-hour period. The L_{max} is the highest root mean squared (RMS) sound pressure level within the sampling period, and the L_{min} is the lowest RMS sound pressure level within the measuring period (Crocker 2007). Normal conversational levels are in the 60 to 65 dBA L_{eq} range; ambient noise levels greater than 65 dBA L_{eq} can interrupt conversations (Federal Transit Administration [FTA] 2018).

Noise that occurs at night tends to be more disturbing than that occurring during the day. Community noise is usually measured using Day-Night Average Level (DNL), which is the 24-hour average noise level with a +10-dBA penalty for noise occurring during nighttime hours (10:00 p.m. to 7:00 a.m.). Community noise can also be measured using Community Noise Equivalent Level (CNEL), which is the 24-hour average noise level with a +5-dBA penalty for noise occurring from 7:00 p.m. to 10:00 p.m. and a +10-dBA penalty for noise occurring from 10:00 p.m. to 7:00 a.m. (Caltrans 2013). Noise levels described by DNL and CNEL usually differ by about 1 dBA. Quiet suburban areas typically have CNEL noise levels in the range of 40 to 50 CNEL, while areas near arterial streets are in the 50 to 60+ CNEL range.

2.2 Vibration

Groundborne vibration of concern in environmental analysis consists of the oscillatory waves that move from a source through the ground to adjacent structures. The number of cycles per second of oscillation makes up the vibration frequency, described in terms of Hz. The frequency of a vibrating object describes how rapidly it oscillates. The normal frequency range of most groundborne vibration that can be felt by the human body is from a low of less than 1 Hz up to a high of about 200 Hz (Crocker 2007).

While people have varying sensitivities to vibrations at different frequencies, in general they are most sensitive to low-frequency vibration. Vibration in buildings, such as from nearby construction activities, may cause windows, items on shelves, and pictures on walls to rattle. Vibration of building components can also take the form of an audible low-frequency rumbling noise, referred to as groundborne noise (FTA 2018). Although groundborne vibration is sometimes noticeable in outdoor environments, it is almost never annoying to people who are outdoors. The primary concern from vibration is that it can be intrusive and annoying to building occupants and vibration-sensitive land uses.

Vibration energy spreads out as it travels through the ground, causing the vibration level to diminish with distance away from the source. High-frequency vibrations diminish much more rapidly than low frequencies, so low frequencies tend to dominate the spectrum at large distances from the source. Discontinuities in the soil strata can also cause diffractions or channeling effects that affect the propagation of vibration over long distances (Caltrans 2020). When a building is impacted by vibration, a ground-to-foundation coupling loss will usually reduce the overall vibration level. However, under rare circumstances, the ground-to-foundation coupling may actually amplify the vibration level due to structural resonances of the floors and walls.

Vibration amplitudes are usually expressed in peak particle velocity (PPV) or RMS vibration velocity. The PPV and RMS velocity are normally described in inches per second (in/sec). PPV is defined as the maximum instantaneous positive or negative peak of a vibration signal. PPV is often used in monitoring of blasting vibration because it is related to the stresses that are experienced by buildings (Caltrans 2020). Table 3 summarizes the vibration damage threshold criteria recommended by Caltrans for structural damage to buildings.

Table 3 Vibration Damage Potential Threshold Criteria

Structure and Condition	Vibration Level (in/sec PPV)	
	Transient Sources	Continuous/Frequent Intermittent Sources
Extremely fragile historic buildings, ruins, ancient monuments	0.12	0.08
Fragile buildings	0.2	0.1
Historic and some old buildings	0.5	0.25
Older residential structures	0.5	0.3
New residential structures	1.0	0.5
Modern industrial/commercial buildings	2.0	0.5

in/sec = inches per second; PPV = peak particle velocity
 Source: Caltrans 2020

In addition to the potential for building damage, the human body responds to vibration signals. However, unlike buildings, which are rigid, it takes some time for the human body to respond to vibration. In a sense, a building responds to the instantaneous movement while the human body responds to average vibration amplitude, which is measured as RMS. The averaging of the particle generally results in the rms conservatively being equivalent to 71 percent of the PPV. Thus, human annoyance usually results in a more restrictive vibration limit than structural damage limits.

Numerous studies have been conducted to characterize the human response to vibration. The vibration annoyance potential criteria recommended for use by Caltrans, which are based on the general human response to different levels of groundborne vibration velocity levels, are described in Table 4.

Table 4 Vibration Annoyance Potential Criteria

Human Response	Vibration Level (in/sec PPV)	
	Transient Sources	Continuous/Frequent Intermittent Sources
Severe	2.0	0.4
Strongly perceptible	0.9	0.10
Distinctly perceptible	0.25	0.04
Barely perceptible	0.04	0.01

Source: Caltrans 2020

2.3 Sensitive Receivers

Noise exposure goals for various types of land uses reflect the varying noise sensitivities associated with those uses. The Santa Clarita General Plan Noise Element identifies noise-sensitive land uses as housing, schools, medical facilities, libraries, social care facilities, and similar facilities (City of Santa Clarita 2011). The nearest existing sensitive receivers are single-family homes located approximately 200 feet west of the project site and the nearest planned sensitive receivers are residences sited approximately 100 feet north of the project site as part of the Vista Canyon Mixed-Use Project, which is currently under construction. Additional sensitive receivers include residences approximately 250 feet south of the project site across the Union Pacific Railroad tracks.

2.4 Project Noise Setting

The most prevalent source of noise in the project site vicinity is vehicular traffic on Lost Canyon Road to the west, SR 14 to the west and north, and the Union Pacific Railroad to the south. In addition, Harriman Street, a newly constructed street for the Vista Canyon Mixed-Use Project located north of the project site, will be a source of vehicular traffic noise once the Vista Canyon Mixed-Use Project becomes operational. Ambient noise levels are generally highest during the daytime and rush hours unless congestion substantially slows speeds, which tends to reduce ambient noise levels.

To characterize ambient sound levels at and near the project site, four 15-minute sound level measurements were conducted on Tuesday, February 4, 2020 during the PM peak hour between 4:23 p.m. and 5:58 p.m. An Extech, Model 407780A, ANSI Type 2 integrating sound level meter was used to conduct the measurements. Figure 4 shows the noise measurement location, and Table 5 summarizes the results of the noise measurements. Detailed sound level measurement data are included in Appendix A.

Table 5 Project Site Sound Level Monitoring Results

#	Measurement Location	Sample Times	Approximate Distance to Primary Noise Source	L _{eq} (dBA)
1	Lost Canyon Road north of Medley Ridge Drive	4:23 – 4:38 p.m.	40 feet from centerline of Lost Canyon Road	53
2	Eastern terminus of Shauna Way	5:43 –5:58 p.m.	30 feet from centerline of Shauna Way	45
3	Western boundary of project site along on Lost Canyon Road	4:45 –5:00 p.m.	45 feet from centerline of Lost Canyon Road	50
4	Northern terminus of English Oak Court	5:15 –5:27 p.m.	10 feet from centerline of English Oak Court	40

See Appendix A for noise monitoring data. See Figure 4 for noise measurement locations.

Fig 3 Noise Measurement Locations

2.5 Regulatory Setting

City of Santa Clarita Noise Element

The City of Santa Clarita Noise Element contains goals and policies that are designed to include noise control in the planning process in order to maintain compatible land uses with acceptable environmental noise levels and protect Santa Clarita residents from excessive noise. The Noise Element provides Noise and Land Use Compatibility Guidelines as shown in Figure 5 (City of Santa Clarita 2011).

The Noise Element also establishes the following goals and policies that would apply to the proposed project:

Goal N 1: A healthy and safe noise environment for Santa Clarita Valley residents, employees, and visitors.

Objective N 1.1: Protect the health and safety of the residents of the Santa Clarita Valley by the elimination, mitigation, and prevention of significant existing and future noise levels.

Policy N 1.1.1: Use the Noise and Land Use Compatibility Guidelines contained on Exhibit N-8 (reproduced herein as Figure 5), which are consistent with State guidelines, as a policy basis for decisions on land use and development proposals related to noise.

Policy N 1.1.2: Continue to implement the adopted Noise Ordinance and other applicable code provisions, consistent with state and federal standards, which establish noise impact thresholds for noise abatement and attenuation, in order to reduce potential health hazards associated with high noise levels.

Policy N 1.1.3: Include consideration of potential noise impacts in land use planning and development review decisions.

Policy N 1.1.4: Control noise sources adjacent to residential, recreational, and community facilities, and those land uses classified as noise sensitive.

Goal N 2: Protect residents and sensitive receptors from traffic-generated noise.

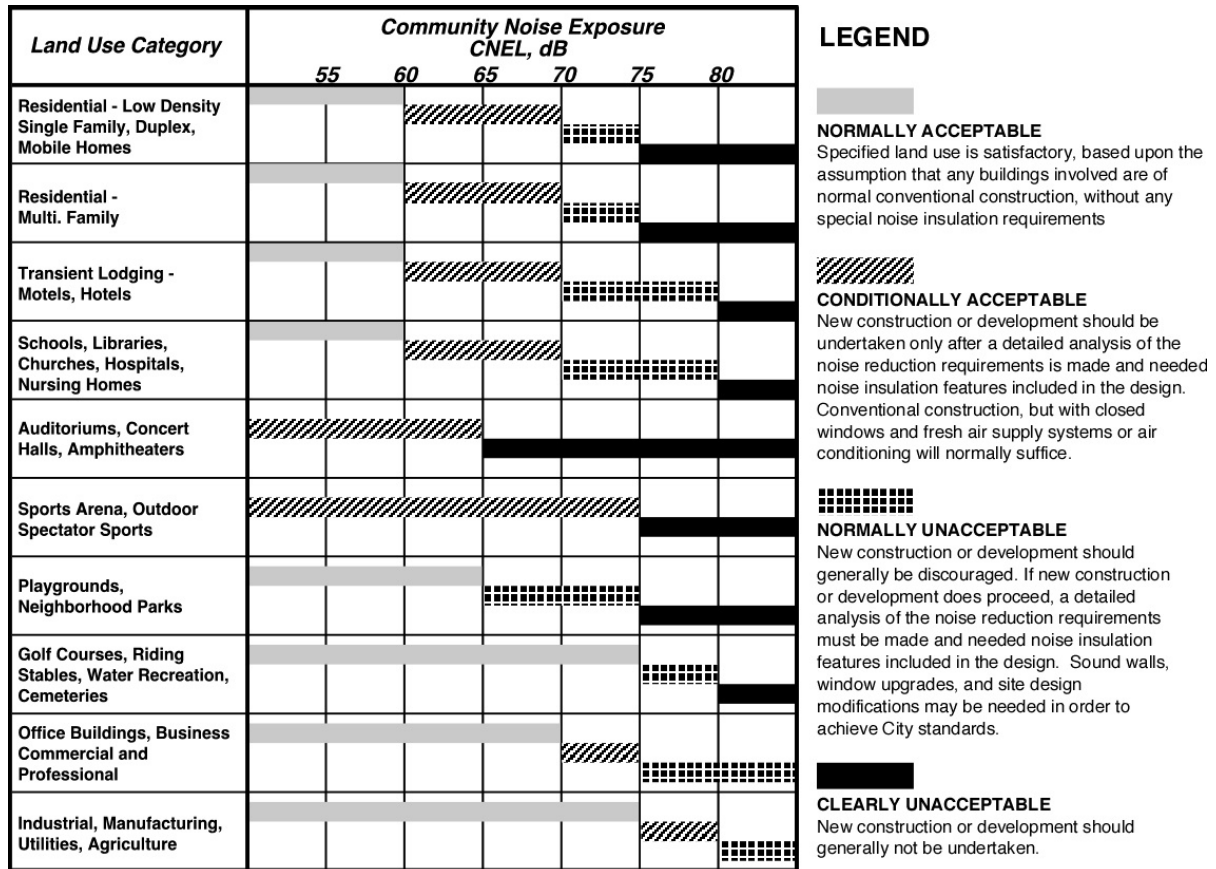

Objective N 2.1: Prevent and mitigate adverse effects of noise generated from traffic on arterial streets and highways through implementing noise reduction standards and programs.

Policy N 2.1.2: Encourage the use of noise absorbing barriers, where appropriate.

Policy N 2.1.4: Reduce significant noise levels related to through-traffic in residential areas by promoting subdivision circulation designs to contain a hierarchy of streets, which efficiently direct traffic to highways.

Policy N 2.1.7: Require vehicle owners to properly maintain their equipment to avoid generating excessive noise levels.

Figure 5 City of Santa Clarita Noise and Land Use Compatibility Guidelines

Goal N 3: Protect residential neighborhoods from excessive noise.

Objective N 3.1: Prevent and mitigate significant noise levels in residential neighborhoods.

Policy N 3.1.1: Require that developers of new single-family and multi-family residential neighborhoods in areas where the ambient noise levels exceed 60 CNEL provide mitigation measures for the new residences to reduce interior noise levels to 45 CNEL, based on future traffic and railroad noise levels.

Policy N 3.1.2: Require that developers of new single-family and multi-family residential neighborhoods in areas where the projected noise levels exceed 65 CNEL provide mitigation measures (which may include noise barriers, setbacks, and site design) for new residences to reduce outdoor noise levels to 65 CNEL, based on future traffic conditions. This requirement would apply to rear yard areas for single-family developments, and to private open space and common recreational and open space areas for multi-family developments.

Policy N 3.1.3: Through enforcement of the applicable Noise Ordinance, protect residential neighborhoods from noise generated by machinery or activities that produce significant discernable noise exceeding recommended levels for residential uses.

Policy N 3.1.4: Require that those responsible for construction activities develop techniques to mitigate or minimize the noise impacts on residences and adopt standards that regulate noise from construction activities that occur in or near residential neighborhoods.

Policy N 3.1.7: Ensure that design of parks, recreational facilities, and schools minimize noise impacts to residential neighborhoods.

Santa Clarita Municipal Code

SCMC Section 11.44.040(A-B). Santa Clarita Municipal Code (SCMC) Section 11.44.040(A) sets exterior noise level limits for residential, commercial, and manufacturing land uses, which are summarized in Table 6. SCMC Section 11.44.040(B) provides corrections to the noise level limits for certain noise conditions, which are summarized in Table 7. These corrections may be applied to the increase or decrease the numerical noise level limits shown in Table 6 where applicable noise conditions exist.

Table 6 Noise Level Limits

Region	Time	L _{eq} (dBA)
Residential	Day ¹	65
	Night ²	55
Commercial/Manufacturing	Day ¹	80
	Night ²	70

¹ SCMC Section 11.44.020 defines “Day” as 7:00 a.m. to 9:00 p.m.

² SCMC Section 11.44.020 defines “Night” as 9:00 p.m. to 7:00 a.m.

Source: SCMC Section 11.44.040(A)

Table 7 Corrections to Noise Limits

Noise Condition	Correction (in dB)
Repetitive Impulsive Noise	-5
Steady Whine, Screech or Hum	-5
Noise Occurring More Than 5 But Less Than 15 Minutes Per Hour ¹	+5
Noise Occurring More Than 1 But Less Than 5 Minutes Per Hour ¹	+10
Noise Occurring Less Than 1 Minute Per Hour ¹	+20

¹ These corrections apply to daytime noise level limits only.

Source: SCMC Section 11.44.040(B)

SCMC Section 11.44.060(A). It shall be unlawful for any person within the City to use or operate any radio receiving set, musical instrument, phonograph, television set, or other machine or device for the producing or reproducing of sound at any time in such a manner as to produce noise levels on residential land which would disturb the peace, quiet and comfort of neighboring residents or any reasonable person of normal sensitivity residing in the area.

SCMC Section 11.44.070. Any noise level from the use or operation of any machinery, equipment, pump, fan, air conditioning apparatus, refrigerating equipment, motor vehicle, or other mechanical or electrical device, or in repairing or rebuilding any motor vehicle, which exceeds the noise limits as set forth in Section 11.44.040 at any property line, or, if a condominium or rental units, within any condominium or rental unit within the complex, shall be a violation of this chapter.

SCMC Section 11.44.080. No person shall engage in any construction work which requires a building permit from the City on sites within 300 feet of a residentially zoned property except between the hours of 7:00 a.m. to 7:00 p.m., Monday through Friday, and 8:00 a.m. to 6:00 p.m. on Saturday. Further, no work shall be performed on the following public holidays: New Year's Day, Independence Day, Thanksgiving, Christmas, Memorial Day, and Labor Day. Emergency work as defined in SCMC Section 11.44.020(D) is permitted at all times. The Department of Community Development may issue a permit for work to be done "after hours"; provided, that containment of construction noises is provided.

SCMC Section 11.44.090. The noise limits as described in SCMC Section 11.44.040(A) shall apply to any use of sound-amplifying equipment.

SCMC Section 17.57.020(E). For residential properties and structures, all air conditioners, antennas, heating, cool and ventilating equipment, and all other mechanical, lighting, or electrical devices shall be screening, shielded and/or sound buffered from surrounding properties and streets.

3 Impact Analysis

3.1 Methodology

Construction Noise

Construction noise was estimated using the FHWA Roadway Construction Noise Model (RCNM) (2006). RCNM predicts construction noise levels for a variety of construction operations based on empirical data and the application of acoustical propagation formulas. Using RCNM, construction noise levels were estimated at noise-sensitive receivers near the project site. RCNM provides reference noise levels for standard construction equipment, with an attenuation rate of 6 dBA per doubling of distance for stationary equipment.

For construction noise assessment, construction equipment can be considered to operate in two modes: stationary and mobile. As a rule, stationary equipment operates in a single location for one or more days at a time, with either fixed-power operation (e.g., pumps, generators, and compressors) or variable-power operation (e.g., pile drivers, rock drills, and pavement breakers). Mobile equipment moves around the construction site with power applied in cyclic fashion, such as bulldozers, graders, and loaders (FTA 2018). Noise impacts from stationary equipment are assessed from the center of the equipment, while noise impacts from mobile construction equipment are assessed from the center of the equipment activity area (e.g., construction site).

Variation in power imposes additional complexity in characterizing the noise source level from construction equipment. Power variation is accounted for by describing the noise at a reference distance from the equipment operating at full power and adjusting it based on the duty cycle, or percent of operational time, of the activity to determine the L_{eq} of the operation (FTA 2018).

Each phase of demolition and construction has a specific equipment mix, depending on the work to be accomplished during that phase. Each phase also has its own noise characteristics; some will have higher continuous noise levels than others, and some may have high instantaneous noise levels. The maximum hourly L_{eq} of each phase is determined by combining the L_{eq} contributions from each piece of equipment used in that phase (FTA 2018).

Construction of the proposed multi-family residential units is estimated to occur over 61 months. Construction phases would include site preparation, grading, drainage, and utilities installation and paving for the entire site followed by building construction and architectural coating, which would occur at different times throughout the project site as buildings are constructed in phases. Construction would not require any blasting or pile driving. The construction equipment list for each phase was provided by the project applicant. It is assumed that diesel engines would power all construction equipment. For assessment purposes, and to be conservative, the maximum hourly noise level that would occur during of all phases of construction activities has been used for assessment. Noise levels during the loudest hour are based on the use of two excavators, a forklift, four air compressors, and four generators operating simultaneously during the building construction phase. Using the FHWA RCNM to estimate noise associated with construction equipment, maximum hourly noise levels were calculated to be approximately 86 dBA L_{eq} at 50 feet. Due to the dynamic nature of construction, maximum hourly noise levels were calculated from the center of each construction activity area. Because buildings would be constructed in phases at different locations

on the project site depending on the type of housing, maximum hourly noise levels were calculated for each type of housing at the nearest sensitive receivers at the following distances:

- Townhomes – approximately 210 feet (planned residences to the north)²
- Market Rate All-Ages Apartments – approximately 430 feet (residences to the west)
- Deed Restricted Affordable Senior Apartments – approximately 480 feet (existing residences to the south)
- Age-Qualified Apartments – approximately 690 feet (existing residences to the west)

RCNM calculations are included in Appendix B.

Off-site Traffic Noise

The project would generate approximately 2,540 daily vehicle trips, thereby increasing traffic on area roadways (Zhou 2020a). To determine project impacts to roadway noise levels, roadway noise was modeled using the FHWA Traffic Noise Model (TNM) spreadsheet.³ Roadway noise was modeled under existing, future, and future plus project conditions along Lost Canyon Road and Jakes Way based on traffic counts and modeling prepared by Fehr & Peers (Zhou 2020b). These locations were selected for modeling because they would be the most affected by project-generated traffic, capture potential roadway noise impacts to residential uses, and existing and future ADT volumes for these locations are provided in the traffic impact study prepared for the project. Based on the nature of the roadways, it was assumed that the vehicle mix of ADT on both roadways is 97 percent cars, 2 percent medium trucks, and 1 percent heavy trucks. Additional model assumptions include standard estimates of 5 percent of daily trips occurring in the evening and 15 percent of daily trips occurring at night and vehicle speeds consistent with posted speed limits on the modeled roadways.

Because residences along Jakes Way have direct line-of-sight to SR 14, this analysis includes traffic noise levels generated by SR 14 in the evaluation of existing and cumulative traffic noise levels along Jakes Way. According to Exhibit N-7 in the City's Noise Element, residences along Jakes Way between Lost Canyon Road and Eleanor Circle would be exposed to traffic noise levels of approximately 60 CNEL under existing and cumulative (i.e., future) conditions (City of Santa Clarita 2011).

Noise/Land Use Compatibility

In accordance with Policy N.3.1.1 of the City's General Plan Noise Element, the noise/land use compatibility of the project site was evaluated by comparing estimated ambient noise levels under cumulative plus project traffic and railroad conditions to the City's noise/land use compatibility standards for multi-family land uses (see Figure 5 in Section 2.5, *Regulatory Setting*). For cumulative plus project conditions, the FHWA TNM spreadsheet calculations discussed under *Off-site Traffic Noise* were utilized to estimate roadway noise levels and the U.S. Department of Housing and Urban Development Day/Night Noise Level Electronic Assessment Tool (HUD DNL Calculator) was used to approximate railway noise levels. The HUD DNL Calculator analyzes railway noise based on distance to the train tracks, average train speed, engines per train, railway cars per train, number of trains

² Townhomes would be constructed in 13 sub-phases; therefore, to provide a conservative estimate of project impacts, noise levels were estimated from the center of the townhouse block closest to sensitive receivers.

³ The FHWA TNM spreadsheet relies on version 2.5. The differences between TNM version 2.5 and version 3.0 do not affect the calculations made in the TNM spreadsheet.

per day, the percentage of trains at night, the presence of whistles and horns, and if the tracks have bolted or welded tracks. This analysis includes the following assumptions:

- All trains are diesel-powered.
- Tracks are bolted.
- Horns and whistles are not used by trains because there are no public grade crossings within one mile of the project site.
- Passenger trains:
 - The average train speed adjacent to the project site is 15 miles per hour as trains accelerate or decelerate into the station.
 - Each passenger train has one engine and four railway cars, which was assumed to be typical of Metrolink trains.
 - The Metrolink Antelope Valley line will serve approximately 48 trains per day upon project buildout (Metrolink 2016).⁴
 - Based on current nighttime operations on the Antelope Valley line (Metrolink 2019b), approximately 19 percent of trains will pass by the project site during nighttime hours (10:00 p.m. to 7:00 a.m.).
- Freight trains:
 - The average train speed is 25 miles per hour (Union Pacific Corporation 2019).
 - Each freight train has two engines and 116 railway cars (Union Pacific Corporation 2019).⁵
 - Up to 25 trains will pass by the project site per day upon project buildout (Caltrans 2018).
 - This analysis assumes a model default night fraction of 15 percent for freight rail.

Groundborne Vibration

The proposed project does not include substantial vibration sources associated with operation. Thus, construction activities have the greatest potential to generate groundborne vibration affecting nearby receivers, especially during grading and paving of the project site. The greatest vibratory sources during construction would be rollers, bulldozers, and loaded trucks. Neither blasting nor pile driving would be required for construction of the proposed project. Construction vibration estimates are based on vibration levels reported by Caltrans and the FTA (Caltrans 2020; FTA 2018).

A quantitative assessment of potential vibration impacts from construction activities was conducted using the estimates and equations developed by Caltrans and the FTA (Caltrans 2020, FTA 2018). Table 8 shows typical vibration levels for various pieces of construction equipment used in the assessment of construction vibration (FTA 2018). These pieces of construction equipment are anticipated to be used during project construction and would generate the highest levels of vibration as compared to construction equipment not included in this analysis.

⁴ This analysis assumes the moderate growth scenarios of the Metrolink 10-Year Strategic Plan in which the number of daily trains along the Antelope Valley line increases from 30 to 48 trains (Metrolink 2016).

⁵ The average train length was estimated by averaging the train lengths of intermodal, grain, manifest, automotive, and coal trains (Union Pacific 2019).

Table 8 Vibration Levels Measured during Construction Activities

Equipment	PPV at 25 Feet (in/sec)
Vibratory Roller	0.21
Large Bulldozer	0.089
Loaded trucks	0.076

PPV = peak particle velocity
 Source: FTA 2018

3.2 Significance Thresholds

To determine whether a project would have a significant noise impact, Appendix G to the *State CEQA Guidelines* requires consideration of whether a project would result in:

1. Generation of a substantial temporary or permanent increase in ambient noise levels in the vicinity of the project in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies;
2. Generation of excessive groundborne vibration or groundborne noise levels; or
3. For a project located within the vicinity of a private airstrip or an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, exposure of people residing or working in the project area to excessive noise levels.

Construction Noise

Per SCMC Section 11.44.080, noise generated by construction activities is exempt from compliance with the noise level limits contained in SCMC Section 11.44.040 if they occur between the hours of 7:00 a.m. to 7:00 p.m., Monday through Friday and 8:00 a.m. to 6:00 p.m. on Saturday. However, for purposes of analyzing impacts from this project, the FTA *Transit Noise and Vibration Impact Assessment Manual* (FTA 2018) criteria will be used. The FTA provides reasonable criteria for assessing construction noise impacts based on the potential for adverse community reaction. For residential uses, the daytime noise threshold is 80 dBA L_{eq} for an 8-hour period (FTA 2018).

On-site Operational Noise

Operational noise generated by the proposed project would be significant if it would exceed the noise level limits specified in SCMC Section 11.44.040 (see Table 6 and Table 7).

Off-site Traffic Noise

Traffic noise impacts are evaluated in consideration of the City’s Noise and Land Use Compatibility Guidelines (see Figure 5) and community response to changes in ambient noise levels. As discussed in Section 2.1, *Overview of Sound Measurement*, the average healthy ear can barely perceive an increase of up to 3 dBA in noise levels, and a change of 5 dBA is readily perceptible. Based on this information, off-site traffic noise impacts would be significant if project-related traffic would result if one of the following would occur:

- A noise level increase of 5 dBA or greater if noise levels remain within the same land use compatibility classification;

- A noise level increase of 3 dBA or greater if noise levels change land use compatibility classifications;
- Any increase in noise levels if existing noise levels fall within the “normally unacceptable” or “clearly unacceptable” ranges.

Vibration

The City of Santa Clarita has not adopted standards to assess vibration impacts during construction and operation. However, Caltrans has developed limits for the assessment of vibrations from transportation and construction sources. The Caltrans vibration limits are reflective of standard practice for analyzing vibration impacts on structures from continuous and intermittent sources. As shown in Section 2.2, *Vibration*, the Caltrans (2020) *Transportation and Construction Vibration Guidance Manual* identifies three sets of impact criteria for buildings and humans. Table 3 presents the impact criteria for buildings, and Table 4 presents impact criteria for humans from construction and operational vibration sources. The thresholds of significance used in this analysis to evaluate vibration impacts are based on these impact criteria, as summarized in Table 9.

Table 9 Vibration Thresholds

Type of Impact	Thresholds for Occasional Pass-bys of Construction Equipment (in/sec PPV) ¹	Thresholds for Extended Construction Activities and Operational Activities (in/sec PPV) ¹
Human Annoyance ¹	0.24	0.04
Damage to Older Residential Structures	0.5	0.3
Damage to Newer Residential Structures	1.0	0.5

¹ Thresholds are based on the points at which transient and steady state vibrations are distinctly perceptible from other vibrations.

3.3 CEQA Impact Analysis

Threshold 1: Would the proposed project generate a substantial temporary or permanent increase in ambient noise levels in the vicinity of the project in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies?

Impact N-1 CONSTRUCTION OF THE PROPOSED PROJECT WOULD EXPOSE NEARBY SENSITIVE RECEIVERS TO A TEMPORARY INCREASE IN NOISE. HOWEVER, CONSTRUCTION NOISE LEVELS WOULD NOT EXCEED THE CITY OF SANTA CLARITA CONSTRUCTION NOISE THRESHOLDS. THEREFORE, THE PROPOSED PROJECT WOULD HAVE A LESS THAN SIGNIFICANT CONSTRUCTION NOISE IMPACT.

Construction Noise

Noise levels during the loudest hour of construction would occur during the building construction phase during which two excavators, a forklift, four air compressors, and four generators may operate simultaneously. As discussed in Section 3.1, *Methodology*, buildings would be constructed in phases; therefore, maximum hourly noise levels were calculated for each phase at the nearest

sensitive receivers using the FHWA RCNM and assuming a standard distance attenuation rate of 6 dBA per doubling of distance. Table 10 summarizes estimated construction noise levels. As shown therein, construction noise levels would not exceed the daytime construction noise threshold of 80 dBA L_{eq} at the nearest sensitive receivers. Construction noise levels at other nearby sensitive receivers would be less than the noise levels at the nearest sensitive receiver due to distance attenuation. Therefore, construction noise impacts would be less than significant.

Table 10 Estimated Construction Noise Levels

Building Construction Phase¹	Distance to Nearest Sensitive Receiver (feet)²	Noise Level (dBA L_{eq})	Threshold (dBA L_{eq})	Threshold Exceeded?
Townhomes	210	74	80	No
Market Rate All-Ages Apartments	430	67	80	No
Deed Restricted Affordable Senior Apartments	480	66	80	No
Age-Qualified Apartments	690	63	80	No

¹ Although some types of housing units would be constructed within the same general timeframe, the same set of construction equipment would be used for the different housing types. There would not be two sets of construction equipment operating simultaneously at two different locations on the project site.

² Because buildings would be constructed in phases at different locations on the project site depending on the type of housing, maximum hourly noise levels were calculated for each type of housing at the distance from the proposed building locations on-site to the nearest sensitive receivers.

See Appendix B for RCNM results.

On-Site Operational Noise

The project would include ground-level HVAC equipment. One HVAC unit would be provided for each townhome, and several apartment units would share a larger HVAC unit. Assuming approximately one ton of HVAC systems would be required for every 600 square feet of apartment floor space, the proposed apartments would require approximately 431 tons of HVAC systems, or approximately 86 HVAC units.^{6, 7} HVAC equipment would be located as close as 145 feet from the property line of the nearest sensitive receiver, which are planned residences part of the Vista Canyon Mixed-Use Project. HVAC equipment is a continuous noise source, and noise levels from a single HVAC unit can reach up to 70 dBA L_{eq} at a distance of 15 feet from the source (Illingworth & Rodkin 2009). At a distance of 145 feet, each HVAC unit would generate a noise level of approximately 50 dBA L_{eq} . However, SCMC Section 17.57.020(E) requires all HVAC equipment on residential properties to be screened, shielded and/or sound buffered. A noise barrier can achieve a minimum 5-dB reduction when it breaks the line-of-sight between the noise source and the receiver (FHWA 2011). Accordingly, HVAC screening would reduce noise levels by at least 5 dBA to approximately 45 dBA L_{eq} for each unit. Based on the proposed project's site design, any planned residence to the north would be exposed to noise from approximately 7 HVAC units. Assuming worst-case exposure of noise from up to 7 HVAC units each at a distance of 145 feet, combined

⁶ The ratio of tons of HVAC systems to square feet is based on the average of the low-end estimates (one ton per 400 square feet for less efficient systems and one ton per 800 square feet for more efficient systems) for determining HVAC system size (United States Department of Energy 2010).

⁷ 258,701 multi-family residential square feet divided by 600 square feet per ton of HVAC system

noise levels generated by HVAC equipment at the nearest sensitive receiver would be approximately 54 dBA L_{eq} , which would not exceed the daytime standard of 65 dBA L_{eq} for residential land uses or the nighttime standard of 55 dBA L_{eq} for residential land uses. Therefore, impacts related to HVAC noise would be less than significant.

The proposed project would require periodic trash hauling services. However, the project involves development of an infill site surrounded by residential land uses, which currently require trash hauling services. Therefore, these activities would not result in a substantial permanent increase in ambient noise levels, and impacts would be less than significant.

On-site vehicle circulation would generate intermittent noise as vehicles travel throughout the site. During peak hour traffic, approximately 190 vehicles would enter and exit the project site (Zhou 2020). The hourly noise level for on-site circulation of 190 vehicles traveling 25 miles per hour (the residential speed limit) is approximately 39 dBA L_{eq} at 50 feet from the source (Federal Highway Administration 2017).⁸ Vehicle circulation areas on-site would be approximately 100 feet from the nearest sensitive receivers to the north of the project site. Therefore, the hourly noise level for on-site vehicle circulation during peak hour traffic would be approximately 36 dBA L_{eq} at the nearest sensitive receivers, which would not exceed the City's residential daytime or nighttime noise level limits of 65 dBA L_{eq} or 55 dBA L_{eq} , respectively. Therefore, impacts from vehicle circulation and parking noise would be less than significant.

The project would include common recreational spaces, including parks, pools, courtyards, and landscaped walkways. Noise at these areas would include social conversations and children playing. Per SCMC Section 14.06.130, it would be unlawful to use sound-amplifying devices in the on-site parks; therefore, this potential noise source is not included in this analysis. Average noise levels from social conversations and children playing are approximately 60 dBA at 50 feet for approximately 20 children playing and approximately 63 dBA L_{eq} at three feet for 20 people talking simultaneously (County of Sacramento 2011; American Journal of Audiology 1998). For the purposes of this analysis, it is assumed that peak operations of the main park on the eastern portion of the project site would consist of approximately 20 children utilizing the playground and approximately 100 people utilizing the picnic and seating areas (40 people in southern area, 20 people in northern area, and 40 people in eastern area based on proposed seating capacity indicated on the site plan shown in Figure 3). Sensitive receivers nearest to the project's main park would be the planned apartments to the north that are part of the Vista Canyon Mixed-Use Project, located approximately 40 feet from the playground, 180 feet from the northern picnic area, 230 feet from the northern part of the southern picnic area, 240 feet from the southern part of the southern picnic area, and 280 feet from the eastern picnic area. At these receivers, peak park operations would generate a noise level of approximately 54 dBA L_{eq} , which would not exceed the City's residential daytime noise level limit of 65 dBA L_{eq} (see Appendix C for recreational noise modeling). Although it is unlikely that peak park operations would occur during nighttime hours (9:00 p.m. to 7:00 a.m.), this noise level also would not exceed the City's residential nighttime noise level limit of 55 dBA L_{eq} . Noise levels at the sensitive receivers closest to other outdoor use areas dispersed throughout the project site would be less than noise levels generated by the project's main park due to the smaller size /capacity of these outdoor use areas, greater distance to the nearest sensitive receivers, and, in some instances, attenuation due to shielding by proposed buildings that would block the line of

⁸ The FHWA TNM Low Volume Road Noise Calculation Tool relies on TNM version 2.5. A similar tool is not yet available for TNM version 3.0.

sight between outdoor use areas and sensitive receivers. Therefore, impacts from recreational activity noise would be less than significant.

Off-Site Traffic Noise

Table 11 summarizes traffic noise levels under existing and existing plus project conditions along Jakes Way and Lost Canyon Road. As shown therein, project-related traffic would not increase ambient noise levels by more than 5 dBA or result in a change in land use compatibility classifications for sensitive receivers along these roadways, all of which fall within the “normally acceptable” and “conditionally acceptable” noise level ranges. Therefore, project-related traffic would result in less-than-significant impacts to traffic noise levels.

Table 11 Existing Plus Project Roadway Noise Levels

Location	Estimated Roadway Noise (CNEL)		Change in Noise (dBA)	Noise Increase Threshold (dBA)	Threshold Exceeded?
	Existing	Existing + Project			
Jakes Way between Lost Canyon Road and Sierra Highway ¹	60	60	+ <1	+ 5	No
Lost Canyon Road between Jakes Way and Medley Ridge Drive	51	55	+ 4	+ 5	No
Lost Canyon Road between Medley Ridge Drive and Winter Pine Way	60	61	+ 1	+ 5	No
Lost Canyon Road between Winter Pine Way and Canyon Park Boulevard	62	63	+ 1	+ 5	No
Lost Canyon Road between Canyon Park Boulevard and Via Princessa	64	64	+ <1	+ 5	No
Lost Canyon Road between Jakes Way and Sand Canyon Road	64	64	+ <1	+ 5	No

Notes: CNEL = Community Noise Equivalent Level; dBA = A-weighted decibel

¹ Modeled noise levels for existing and existing plus project traffic volumes (35 CNEL and 44 CNEL, respectively) were added to estimated noise levels generated by traffic on SR 14 (60 CNEL) from the City’s Noise Element (2011) to estimate overall roadway noise levels along Jakes Way.

See Appendix D for TNM output results.

Table 12 summarizes traffic noise levels under cumulative and cumulative plus project conditions along Jakes Way and Lost Canyon Road. As shown therein, a cumulative traffic noise impact would

occur along Lost Canyon Road between Jakes Way and Medley Ridge Drive because cumulative plus project traffic noise levels would result in greater than a 3-dBA increase in traffic noise levels as well as a change in the land use compatibility classification from “normally acceptable” to “conditionally acceptable.” The cumulative traffic noise impact would occur as a result of an increase in daily traffic volumes from approximately 450 daily trips under existing conditions to approximately 7,460 daily trips under cumulative plus project conditions, primarily due to buildout of the Vista Canyon Mixed-Use Project to the north of the project site as well as the proposed project.⁹ However, project-related traffic would only contribute approximately 1 dBA to the overall 12-dBA noise level increase. As discussed in Section 2.1, *overview of Sound Measurement*, an increase of up to 3 dBA in noise levels is barely perceptible to the human ear; therefore, a 1-dBA increase in roadway noise levels would not be perceptible. Furthermore, the project’s 1-dBA contribution to cumulative roadway noise would be well below the roadway noise impact threshold of 3 dBA. Therefore, project-related traffic would not result in a cumulatively considerable increase in traffic noise levels along Lost Canyon Road. Significant cumulative traffic noise impacts would not occur along any of the remaining roadways in the study area.

⁹ Estimates of daily traffic volumes are based on an industry standard assumption that peak hour traffic volumes are approximately 10 percent of average daily traffic volumes.

Table 12 Cumulative Plus Project Roadway Noise Levels

Location	Estimated Roadway Noise Levels (CNEL)			Cumulative Change in Noise Levels (dBA)	Noise Level Increase Threshold (dBA)	Threshold Exceeded?	Project Contribution to Cumulative Change (dBA)
	Existing	Cumulative	Cumulative + Project				
Jakes Way between Lost Canyon Road and Sierra Highway ¹	60	62	62	+ 2	+ 5	No	+ <1
Lost Canyon Road between Jakes Way and Medley Ridge Drive	51	63	63	+ 12	+ 3	Yes	+ 1
Lost Canyon Road between Medley Ridge Drive and Winter Pine Way	60	64	64	+ 4	+ 5	No	+ <1
Lost Canyon Road between Winter Pine Way and Canyon Park Boulevard	62	65	65	+ 3	+ 5	No	+ <1
Lost Canyon Road between Canyon Park Boulevard and Via Princessa	64	66	66	+ 2	+ 5	No	+ <1
Lost Canyon Road between Jakes Way and Sand Canyon Road	64	65	65	+ 1	+ 5	No	+ <1

Notes: CNEL = Community Noise Equivalent Level; dBA = A-weighted decibel

¹ Modeled noise levels for existing, cumulative, and cumulative plus project traffic volumes (35 CNEL, 58 CNEL, and 58 CNEL, respectively) were added to estimated noise levels generated by traffic on SR 14 (60 CNEL) from the City's Noise Element (2011) to estimate overall roadway noise levels along Jakes Way.

See Appendix D for TNM output results.

Threshold 2: Would the proposed project generate excessive groundborne vibration or groundborne noise levels?

Impact N-2 CONSTRUCTION OF THE PROPOSED PROJECT WOULD EXPOSE NEARBY SENSITIVE RECEIVERS TO A TEMPORARY INCREASE IN VIBRATION. HOWEVER, VIBRATION LEVELS WOULD NOT EXCEED THE HUMAN ANNOYANCE OR STRUCTURAL DAMAGE THRESHOLDS FOR OCCASIONAL PASS-BYS OF CONSTRUCTION EQUIPMENT OR FOR EXTENDED PERIODS OF CONSTRUCTION ACTIVITIES. IN ADDITION, THE PROJECT WOULD NOT

INCLUDE SIGNIFICANT STATIONARY SOURCES OF VIBRATION DURING OPERATION. THEREFORE, THE PROPOSED PROJECT WOULD HAVE A LESS THAN SIGNIFICANT VIBRATION IMPACT.

Construction Vibration

Certain types of construction equipment can generate high levels of groundborne vibration. The equipment utilized during project construction that would generate the highest levels of vibration would include rollers, loaded trucks, and bulldozers. Construction vibration impacts are assessed for individual pieces of construction equipment in accordance with FTA guidance (FTA 2018). Due to site constraints and worker safety limitations, individual pieces of vibratory construction equipment typically do not operate in close proximity to each other such that any single off-site structure would experience substantial levels of vibration from multiple pieces of construction equipment. Therefore, the additive impacts of multiple pieces of vibratory construction equipment operating simultaneously are not evaluated.

Vibration-generating construction equipment that would occasionally pass-by off-site structures would include bulldozers and vibratory rollers used for grading and paving the project site, respectively. These equipment would operate as close as 100 feet from the nearest structure located in the planned residential development immediately north of the project site. Vibration-generating construction equipment that would operate for longer periods of time at the proposed locations of on-site structures would include bulldozers and loaded trucks. These equipment would operate as close as 115 feet from the nearest structure located in the planned residential development immediately north of the project site.

As shown in Table 13, vibration levels from individual pieces of construction equipment would not exceed the human annoyance or structural damage thresholds for occasional pass-bys of construction equipment or for extended periods of construction activities. As a result, impacts would be less than significant.

Table 13 Vibration Levels at Sensitive Receivers

Equipment	Estimated Transient Vibration Levels at Nearest Building (in/sec PPV)¹	Estimated Steady-State Vibration Levels at Nearest Building (in/sec PPV)²
Vibratory Roller	0.05	n/a
Large Bulldozer	0.02	0.02
Loaded Truck	n/a	0.01
Threshold for Human Annoyance	0.24	0.04
Threshold Exceeded?	No	No
Threshold for Structural Damage to Older Residential Structures	0.5	0.3
Threshold Exceeded?	No	No
Threshold for Structural Damage to New Residential Structures	1.0	0.5
Threshold Exceeded?	No	No

Note: Transient vibration levels are estimated for construction activities that would result in infrequent, occasional pass-bys of construction equipment (less than 70 events per day) while steady-state vibration levels are estimated for construction activities that would occur for longer periods of time at a single location on the project site (Caltrans 2020).

¹ Measured at a distance of 100 feet (the distance from the edge of the proposed parking area to the nearest off-site structure).

² Measured at a distance of 115 feet (the distance from the edge of proposed on-site buildings to the nearest off-site structure).

See Appendix E for vibration analysis worksheets.

Operational Vibration

As a residential land use, the proposed project would not include significant stationary sources of vibration, such as manufacturing or heavy equipment operations. No operation-related vibration impact would occur.

Threshold 3: For a project located within the vicinity of a private airstrip or an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the proposed project expose people residing or working in the project area to excessive noise levels?

Impact N-3 THE PROJECT WOULD BE LOCATED OUTSIDE THE AIRPORT INFLUENCE AREA FOR THE WHITEMAN AIRPORT. THEREFORE, THE PROJECT WOULD NOT EXPOSE PEOPLE WORKING IN THE PROJECT AREA TO EXCESSIVE NOISE LEVELS. NO IMPACT WOULD OCCUR.

The nearest airport to the project site is the Whiteman Airport, located approximately 10 miles south of the project site. Therefore, the project would not be within the airport's land use plan, area of influence, within two miles of a public use airport or near a private airstrip or airport (Los Angeles County Airport Land Use Commission 2003). No impacts would occur.

3.4 Noise/Land Use Compatibility Analysis

The ruling for *California Building Industry Association v. Bay Area Air Quality Management District (CBIA v. BAAQMD)* determined that under CEQA, except for a few specified and limited instances, environmental impacts on residents of a proposed project are not required to be analyzed (i.e., CEQA requires the analysis of the impacts of a project on the environment and not analysis of the environment's impacts on a project). Therefore, the following noise/land use compatibility discussion is provided for informational purposes only.

The City of Santa Clarita's General Plan Noise Element considers ambient noise levels up to 60 CNEL to be normally acceptable and ambient noise levels up to 70 CNEL to be conditionally acceptable for multi-family land uses (see Figure 5 in Section 2.5, *Regulatory Setting*). Table 14 summarizes estimated railroad and roadway noise levels at the project site under cumulative plus project conditions. As shown therein, noise levels at residences along the outer edges of the project would experience ambient noise levels ranging from approximately 70 to 75 CNEL, primarily due to noise generated by passenger and freight rail operations. These noise levels would fall within the "conditionally acceptable" and "normally unacceptable" ranges for multi-family residential land uses per the City's noise/land use compatibility criteria (see Figure 5 in Section 2.5, *Regulatory Setting*), and the project would be required to reduce exterior noise levels to 65 CNEL per Policy N 3.1.2 of the City's Noise Element. Furthermore, interior noise levels at residences in the southern portion of the project site would be approximately 50 CNEL, which would exceed the City's standard of 45 CNEL (Policy N.3.1.1 of the City's Noise Element). Therefore, in order to comply with the City's noise/land use compatibility criteria and interior noise standard, the project shall incorporate Recommended Measure N-1, which includes design features to reduce exterior and interior noise exposure.

Table 14 Noise/Land Use Compatibility Analysis

Source	Noise Level (CNEL) ¹			
	Southern Portion of Site	Western Portion of Site	Northern Portion of Site	Eastern Portion of Site
Railroad	75	69	69	69
Lost Canyon Road	58	60	59	n/a
Harriman Street	n/a	n/a	61	61
Total Exterior Noise	75	70	70	70
Interior-to-Exterior Reduction ²	(25)	(25)	(25)	(25)
Total Interior Noise	50	45	45	45

See Appendix D for TNM results and Appendix F for HUD DNL Calculator results.

¹The HUD DNL Calculator calculates noise in L_{dn}; however, L_{dn} and CNEL are interchangeable.

²The exterior-to-interior reduction of new construction with closed windows is typically 25 to 30 dBA (Caltrans 2013). This analysis conservatively utilizes the low end of this range.

Recommended Measure

N-1 Project Design Features for Noise Exposure Reduction

The project shall incorporate the following design features to reduce exterior and interior noise levels on the project site so as to achieve 65 CNEL for exterior noise levels and 45 CNEL for interior noise levels in all habitable rooms:

- A 10-foot-high barrier, berm, or combination thereof should be constructed along the entire length of the southern edge of the project site parallel to the railroad tracks.
- All residences within 270 feet of the railroad should be constructed with upper-level exterior building facades composed of wall and window materials with an elevated composite STC rating that achieves an interior noise level of 45 CNEL.
- All habitable rooms in residential units throughout the project site should be designed and constructed such that any exterior door or window can be kept closed when the room is in use and still receive circulated air. A forced air circulation system (e.g., air conditioning) or active ventilation system (e.g., fresh air supply) should be provided.
- Upper-level balconies for residential units throughout the project site should not be provided on exterior facades with direct line-of-sight to the railroad tracks. Instead, balconies should be provided on northern facades and on facades facing away from the railroad tracks with no direct line-of-sight to the railroad tracks.

Noise Levels with Implementation of Recommendations

Implementation of Recommended Measure N-1 would require implementation of project design features to reduce exterior and interior noise levels. Construction of an approximately 10-foot-high wall would reduce exterior noise levels by approximately 10 dBA to 65 CNEL (see barrier calculations in Appendix F), which would fall within the City’s “conditionally acceptable” range and would be consistent with the exterior noise level standard of 65 CNEL outlined in Policy N 3.1.2 of the City’s Noise Element. The wall would also reduce interior noise levels at the ground floor of residences to

approximately 40 CNEL (65 CNEL – 25 CNEL). In addition, exterior building facades on the upper floors of residences within 270 feet of the railroad would be required to be constructed of window and wall materials with elevated STC ratings to meet the performance criterion of 45 CNEL for interior noise levels . Therefore, these measures would achieve interior noise levels of approximately 45 CNEL or less, which would comply with the City’s standard of 45 CNEL. Therefore, with incorporation of Recommendation Measure N-1, the project would be consistent with the City’s noise/land use compatibility criteria and interior noise standard.

4 Conclusions and Recommendations

The proposed project would have less than significant impacts related to construction noise, operational noise, vibration, off-site traffic noise, and airport-related noise. Exterior noise levels at residences along the outer edges of the project site would fall within the “conditionally acceptable” and “normally unacceptable” ranges for multi-family residential land uses per the City’s noise/land use compatibility criteria. However, implementation of Recommended Measure N-1 would reduce exterior and interior noise exposure to acceptable levels.

Appendix B

Roadway Construction Noise Model (RCNM) Results

Appendix C

Recreational Noise Modeling

Recreational Noise Modeling

Addition

	Children Playing	Southern Picnic Area 1	Southern Picnic Area 2	Northern Picnic Area	Eastern Picnic Area	Total Summed Noise Level (dBA)
1	54.0	25.3	24.2	27.4	23.6	54.0

Appendix D

Traffic Noise Model (TNM) Results

Appendix C Rincon FHWA Traffic Noise Model

Project Name : MetroWalk Santa Clarita		Model Input	
Project Number : 19-07837			
Modeling Condition : Existing			
Ground Type : Hard	Peak ratio to ADT: 10		
Metric (Leq, Ldn, CNEL) : CNEL	Traffic Desc. (Peak or ADT) : Peak		

Segment Number	Roadway	Segment		Traffic Volume	Speed (mph)	Distance to Centerline	Vehicle Cassification Mix (%)					24-Hour Traffic Distribution (%)			K-Factor
		From	To				Automobiles	Motorcycles	Bus	Medium Trucks	Heavy Trucks	Day	Evening	Night	
1	Jakes Way	Sierra Highway	Lost Canyon Road	1	30	40	97			2	1	80	5	15	
2	Lost Canyon Road	Jakes Way	Medley Ridge Drive	45	35	50	97			2	1	80	5	15	
3	Lost Canyon Road	Medley Ridge Drive	Winter Pine Way	389	35	60	97			2	1	80	5	15	
4	Lost Canyon Road	Winter Pine Way	Canyon Park Blvd.	627	35	50	97			2	1	80	5	15	
5	Lost Canyon Road	Canyon Park Blvd.	Via Princessa	916	35	50	97			2	1	80	5	15	
6	Lost Canyon Road	Jakes Way	Sand Canyon Blvd.	832	35	40	97			2	1	80	5	15	

Project Number : MetroWalk Santa Clarita
Modeling Condition : 19-07837
Ground Type : Existing
Metric (Leq, Ldn, CNEL) : CNEL

Model Results

Segment Number	Roadway	Segment		Noise Levels (dB) CNEL					
		From	To	Automobiles	Motorcycles	Bus	Medium Trucks	Heavy Trucks	Total

Noise/Land Use Compatibility Analysis

[Home \(/\)](#) > [Programs \(/programs/\)](#) > [Environmental Review \(/programs/environmental-review/\)](#) > DNL Calculator

DNL Calculator

The Day/Night Noise Level Calculator is an electronic assessment tool that calculates the Day/Night Noise Level (DNL) from roadway and railway traffic. For more information on using the DNL calculator, view the [Day/Night Noise Level Calculator Electronic Assessment Tool Overview \(/programs/environmental-review/daynight-noise-level-electronic-assessment-tool/\)](#).

Guidelines

- To display the Road and/or Rail DNL calculator(s), click on the "Add Road Source" and/or "Add Rail Source" button(s) below.
- All Road and Rail input values must be positive non-decimal numbers.
- All Road and/or Rail DNL value(s) must be calculated separately before calculating the Site DNL.
- All checkboxes that apply must be checked for vehicles and trains in the tables' headers.
- **Note #1:** Tooltips, containing field specific information, have been added in this tool and may be accessed by hovering over all the respective data fields (site identification, roadway and railway assessment, DNL calculation results, roadway and railway input variables) with the mouse.
- **Note #2:** DNL Calculator assumes roadway data is always entered.

Mitigation Options

If your site DNL is in Excess of 65 decibels, your options are:

- **No Action Alternative:** Cancel the project at this location
- **Other Reasonable Alternatives:** Choose an alternate site
- **Mitigation**
 - **Contact your Field or Regional Environmental Officer** (</programs/environmental-review/ HUD-environmental-staff-contacts/>)
 - Increase mitigation in the building walls (only effective if no outdoor, noise sensitive areas)
 - Reconfigure the site plan to increase the distance between the noise source and noise-sensitive uses
 - Incorporate natural or man-made barriers. See *The Noise Guidebook* (</resource/313/hud-noise-guidebook/>)
 - Construct noise barrier. See the **Barrier Performance Module** (</programs/environmental-review/bpm-calculator/>)
